

Voltage Detector IC

Features

- Internal Fixed Threshold
- High Accuracy $\pm 1\%$
- Low Supply Current $1\mu A$
- N-Channel Open-Drain Output
- Low Function Supply Voltage 0.8V
- Delay Time controlled by External Capacitor
- Used to multiple supplies application
- Fully Specified Over Temperature

Applications

- Computers
- Intelligent Instruments
- Portable/Battery-Powered Equipment

General Description

The G623 is a micro-power voltage detector IC used to monitor the multiple power supplies in microprocessor or logic system. It has high-accuracy, low current consumption and adjustable delay. It performs supervisory function by sending out a reset signal whenever the VDD voltage falls below a preset threshold level, and sending out another power detect signal whenever the VCC1, VCC2, or VCC3 power off. Once supplies recovered the threshold level, the reset and power detect signal will be released after a certain delay time controlled by external capacitor.

1. Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

2. Device are ESD sensitive. Handling precaution recommended. The Human Body model is a 100pF capacitor discharged through a 1.5K Ω resistor into each pin.

Block Diagram

Typical Application Circuit

When power pin VDD reaches threshold voltage ($0.9 \times VDD$) from high to low, /RESET pin goes low from high. When any power pin VCC1, VCC2, and VCC3 ramp down over the threshold voltage ($0.8 \times VCCx$), DETECT pin goes low from high. This circuit can set delay time controlled by the external capacitor at the rise of power pin.

$$T_{LH} = CT \times RCT \times \ln\left(\frac{VDD}{VDD - VCTH}\right)$$

T_{LH} : time until the voltage of CDL pin rises to $0.5 \times VDD$ after VDD rises up and beyond the release voltage

CT: CDL pin external capacitor CDLY

RCT: CDL pin internal impedance

Open drain type need pull-up resistor connected to VDD or other power supply.

Because the resistor connected inside VCC3 pin is about $20M\Omega$, suggest that the low side resistor of external resistor divider is smaller than $20k\Omega$ for accuracy.

Layout guideline

Power loops of the Reset IC were considered to minimize the area. If possible, it is suggested to arrange the power loops at the top side copper plane.

(1) Connect the bypass capacitor on VDD, VCC1~3, CDL1~2 as close to the device as possible.
